An iceberg floats in waters off the Antarctic Peninsula. Scientists say satellite readings indicate that Antarctica is undergoing a net reduction in ice mass.

By Robert Roy Britt

LiveScience managing editor

Updated: 2:21 p.m. ET March 2, 2006

Joining the growing list of places on this planet that are melting, Antarctica is losing about 36 cubic miles (150 cubic kilometers) of ice every year, scientists reported Thursday.

For comparison, Los Angeles consumes roughly 1 cubic mile of fresh water a year.

The south polar region holds 90 percent of Earth's ice and 70 percent of the total fresh water on the planet, so any significant pace of melting there is important and could contribute to an already [rising sea](#).

"This is the first study to indicate the total mass balance of the Antarctic ice sheet is in significant decline," said Isabella Velicogna of the University of Colorado at Boulder.

The study — based on satellite measurements made by NASA's Gravity Recovery and Climate Experiment, or GRACE — was detailed Thursday in the online version of the journal Science.

Other studies have documented rapid melting, unprecedented in modern times, in [Greenland](#) and around the [North Pole](#). And rapid [melting of individual glaciers](#) has been noted in Antarctica.

For now, the newly measured melting might seem like a small quantity. The loss of ice in Antarctica amounts to about 0.4 millimeters of global sea rise annually, with a margin of error of 0.2 millimeters, the study concludes. There are about 25 millimeters in an inch.

However, computer models run in 2001 predicted that Antarctica would gain ice during the 21st century due to increased precipitation in a warming climate. The new study, based on satellite measurements between 2002 and 2005, shows the opposite.

Antarctica is twice as large as Australia. The ice sheet, which covers about 98 percent of the continent, has an average thickness of about 6,500 feet — more than a mile.
